

Why Most Red Pandas are Extinct

It is well known that red pandas roam across dense bamboo forests near water. Did you know that red panda's fur is not related to giant pandas? Also there are only 10,000 in the wild but exact number unknown. So why are most of them extinct?

Habitat loss is the main reason that they are becoming extinct. Poaching is also a reason people poach red pandas for medicine, pet trade and their distinctive red fur.

This led to a lot of red pandas dying. Also because of global warming the world is getting hotter. During daylight hours you will see red pandas curled up on tree branches depending on the weather.

Global warming is a problem to the red panda species because when it gets hotter the red pandas will have to climb to higher climates. This means that they will have less food and water. So that the red panda species is declining.

This is why the only red pandas you will see are in zoos, movies and books.
